

ABSTRACT

A one-piece report cover and improved binding structure. The report cover has a front panel, spine and back panel. The improved binding structure comprises a male connector panel, female connector panel and binding element. The female panel has an aperture for receiving and retaining a tab shaped portion of the male panel located between fastening means fastening the female panel to the back panel and a plurality of integrally formed hinges for folding the panel about an edge of a document. The binding element fixes the relationship between the female panel, document and male panel thereby preventing disengagement of the tab portion from the female panel aperture during use. The document may be removed from the improved binding structure by removing the male panel tab portion from the female panel aperture allowing access to the binding element for disassembly. The improved binding structure allows reuse without damage to the components.
